

Lim Xin Hui

Fig.1 Image of my model representing the *Chlorophyllum molybdites* cap

The physical item is a wearable hat which mimics the shape and morphology of the cap of the *Chlorophyllum molybdites* fruiting body. Through modeling the cap and gill morphology in my assignment, I aim to help the public learn to identify this mushroom in the wild via its observable traits.

When creating this mushroom hat, I chose specific colours of beads used and the paint colour to closely mirror what is seen of the fruiting body in the wild. *Chlorophyllum molybdites* is a gilled mushroom, its sporeprint is of a greenish grey hue in mature fruiting bodies (“About Green Gill Mushroom - Maryland Biodiversity Project”, n.d.). I added strings of white beads that reflect green hues when moved. The movement of the beads was designed to mimic spore discharge. I also hope to highlight to the public that spores here are airborne. As the gills turn grey with maturity and finally become greenish brown, this is modelled in the underside of the cap which is painted with lines of brown and green. In the wild the mushroom cap ranges from off white to beige, with brown patches (Lee & Choong, 2023), my mushroom was painted beige with brown centre. Other names of the mushroom include False Parasol, Green-spored Parasol (Lee & Choong, 2023) and Green Gill mushroom (“About Green Gill Mushroom - Maryland Biodiversity Project”, n.d.). The classification of this species includes basidiomycota, agaricomycetes, agaricales, agaricaceae (“*Chlorophyllum molybdites*”, n.d.). This specific species was chosen to make into a hat as it is native to Singapore (“*Chlorophyllum molybdites*”, n.d.).
